

1. Concept of Epoch :

A. one epoch is defined as one iteration which the neural network go through all pair training examples in the training dataset for one time

B. epoch is a kind of hyperparameter.

C. due to the size of learning rate, we cannot get perfectly adjusted weights in one iteration which the neural network go through all pair training examples in the training dataset for one time, so we need to set up the number of epoch [Epoch] to train the neural network with all pair training examples in the training dataset for several times.
