

/ Visualization of Adjustment of Weight for a Perceptron:

A. assuming that inputs (x_0, x_1) and current weights (w_0, w_1) result in z positive, then predicted output P_y is also positive, but desired output y (ground truth) is **negative**, the perceptron learning algorithm will adjust weights (w_0, w_1) to **negative side**, so that the new corresponding z will also move to **negative side** and predicted output P_y will be **negative** finally which match desired output y (ground truth) 's **negative** value.

B.
